# CSCB63 – Design and Analysis of Data Structures

Anya Tafliovich<sup>1</sup>

<sup>&</sup>lt;sup>1</sup>with huge thanks to Anna Bretscher and Albert Lai

Remember this algorithm?

What do we count? Does it matter?

#### Let's try counting this way:

- get/set variables: 1 step
- function call: 1 + steps to evaluate each argument + steps to execute function
- return statement: 1 + steps to evaluate return value
- if/while condition: 1 + steps to evaluate the boolean expression
- assignment statement: 1 + steps to evaluate each side
- ullet arithmetic/comparison/boolean operators: 1+ steps to evaluate each operand
- ullet array access: 1+ steps to evaluate array index
- constants: free!

```
def InsertionSort (A):
                                           STEPS
      i = 1
      while i < len(A):
3
        v = A[i]
                                             5
4
        i = i
5
        while j > 0 and A[j-1] > v:
                                            10 or 3
          A[j] = A[j-1]
6
                                             8
        j = j - 1
8
        A[j] = v
                                             5
        i = i + 1
                                             4
```

What assumptions did we make? Are they realistic?

So, what's the total number of steps?

#### In the worst case:

• line 1: once : 2 steps

#### For n > 1:

- line 2: n-1 times (true) + 1 time (false) : 5n steps
- lines 3, 4, 8, 9: n-1 times : (5+3+5+4)(n-1) = 17n-17 steps
- line 5: for each i: i times (true) + 1 time (false) : 10i + 3 steps
- lines 6, 7: for each i: i times : (8+4)i = 12i steps

$$2 + 5n + 17n - 17 + \sum_{i=1}^{n-1} (10i + 3 + 12i)$$

$$= 22n - 15 + \sum_{i=1}^{n-1} (22i + 3)$$

$$= 22n - 15 + 22\frac{(n-1)n}{2} + 3(n-1)$$

$$= 11n^{2} + 14n - 18$$

#### In the best case:

• line 1: once : 2 steps

#### For $n \geq 1$ :

- line 2: n-1 times (true) + 1 time (false) : 5n steps
- lines 3, 4, 8, 9: n-1 times : (5+3+5+4)(n-1) = 17n-17 steps
- line 5: for each i: 1 time (false): 10 steps
- lines 6, 7: for each *i*: 0 times : 0 steps

$$2 + 5n + 17n - 17 + \sum_{i=1}^{n-1} 10 = 22n - 15 + (n-1)10$$
$$= 32n - 25$$

What if we write the same algorithm differently?

```
0 def InsertionSort (A):
1     n = len(A)
2     for (i = 1; i < n; i++):
3         for (j = i; j > 0 and A[j] < A[j-1]; j--):
4         swap A[j], A[j-1]</pre>
```

• line 1: once, 4 steps

#### For n > 1:

- line 2: 2 steps (once) + 3 steps (n times) + 2 steps (n 1 times)
- line 3: for each i: 3 steps (once) + 11 steps (i times) + 2 steps (once) + 2 steps (i times)
- line 4: for each i: 9 steps (i times)

• line 1: once, 4 steps

For  $n \ge 1$ :

- line 2: 2 steps (once) + 3 steps (n times) + 2 steps (n − 1 times)
- line 3: for each i: 3 steps (once) + 11 steps (i times) + 2 steps (once) + 2 steps (i times)
- line 4: for each i: 9 steps (i times)

$$4 + 2 + 3n + 2(n - 1) + \sum_{i=1}^{n-1} (3 + 11i + 2 + 2i + 9i)$$

$$= 5n + 4 + \sum_{i=1}^{n-1} (22i + 5)$$

$$= 5n + 4 + 22\frac{(n-1)n}{2} + 5n$$

$$= 11n^2 - n + 4$$

Is this the same running time? In what sense?

**Q.** What if I now run this algorithm on a machine that is slower to perform variable look up and write?

Q. Should the complexity change?

**Q.** How important are those constants as the input size n gets large?

**Q.** How are our two results  $11n^2 + 14n - 18$  and  $11n^2 - n + 4$  similar?

**Q.** They are both quadratic polynomials.

We say...

- that a quadratic polynomial is of order  $n^2$ ,
- that a cubic polynomial is of order  $n^3$ ,
- that  $4n \lg(n) + 2n + 10$  is of order  $n \lg(n)$ .

Why can we say this? With a little mathemagic:

$$11n^2 + 14n - 18 \le 11n^2 + 14n \le 11n^2 + 14n^2 = 25n^2$$

Another example:

$$11n^2 - 21n + 19 \le 11n^2 + 19 \le 11n^2 + n \le 11n^2 + n^2 = 12n^2$$

for all natural n > 19

## how long do things take — formally

For all natural  $n \ge 19$ :

$$11n^2 - 21n + 19 \le 12n^2$$

There exists an  $n_0 \in \mathbb{N}$  such that, for all natural  $n \geq n_0$ ,

$$11n^2 - 21n + 19 \le 12n^2$$

We can take this even further and say, there exists real c > 0 and natural  $n_0$  such that, for all natural  $n \ge n_0$ ,

$$11n^2-21n+19\leq c\cdot n^2$$

which is exactly the definition of "Big-Oh"!

# Big-Oh — Asymptotic Upper Bound

#### We denote:

- N: the set of natural numbers
- $\mathbb{R}^+$ : the set of positive real numbers
- $\mathcal{F}$ : the set of functions  $f: \mathbb{N} \to \mathbb{R}^+$

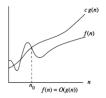

Let  $g \in \mathcal{F}$ . Define  $\mathcal{O}(g)$  to be the set of functions  $f \in \mathcal{F}$  such that

$$\exists c \in \mathbb{R}^+, \exists n_0 \in \mathbb{N}, \forall n \in \mathbb{N}, n \geq n_0 \Rightarrow f(n) \leq c \cdot g(n)$$

## Big-Oh — Asymptotic Upper Bound

Let  $g \in \mathcal{F}$ . Define  $\mathcal{O}(g)$  to be the set of functions  $f \in \mathcal{F}$  such that

$$\exists c \in \mathbb{R}^+, \exists n_0 \in \mathbb{N}, \forall n \in \mathbb{N}, n \geq n_0 \Rightarrow f(n) \leq c \cdot g(n)$$

Let's practice proving a function belongs to big-Oh of another function.

## Big-Oh practice

Suppose we determine an algorithm has running time

$$T(n) = n^3 - n^2 + 5$$

**Prove.**  $T(n) \in O(n^3)$ 

$$n^3 - n^2 + 5 \le n^3 + 5$$

When  $n \geq 5$ ,

$$n^3 + 5 \le n^3 + n \le n^3 + n^3 = 2n^3$$

Let  $n_0 = 5$  and c = 2 so that  $f \in O(n^3)$ .

## Is Big-Oh good enough?

**Q.** Is 
$$12n^2 + 10n + 10 \in O(n^3)$$
?

**Q.** Is 
$$12n^2 + 10n + 10 \in O(n^2 \lg n)$$
?

**Q.** Is 
$$n \in O(n^2)$$
?

**Q.** Is 
$$3 \in O(n^2)$$
?

 $O(n^2)$  includes quadratic functions and "lesser" functions as well.

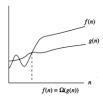

We need another definition to exclude "lesser" functions.

## $Big-\Omega$ — Asymptotic Lower Bound

**Idea.** Want a function g such that for big enough n,

$$0 \le b \cdot g(n) \le f(n)$$

where b is a constant.

**"Big Omega."** Let  $g \in \mathcal{F}$ . Define  $\Omega(g)$  to be the set of functions  $f \in \mathcal{F}$  such that

$$\exists b \in \mathbb{R}^+, \exists n_0 \in \mathbb{N}, \forall n \in \mathbb{N}, n \geq n_0 \Rightarrow f(n) \geq b \cdot g(n) \geq 0$$

Equivalently,  $f \in \Omega(g)$  iff  $g \in O(f)$ .

## Big-Θ — Asymptotic Tight Bound

What if it's both? If  $f \in O(g)$  and  $f \in \Omega(g)$  then we say that  $f \in \Theta(g)$ .

**"Big Theta".** Let  $g \in \mathcal{F}$ . Define  $\Theta(g)$  to be the set of functions  $f \in \mathcal{F}$  such that  $f \in O(g) \cap \Omega(g)$ 

or alternatively,

$$\exists b \in \mathbb{R}^+, \exists c \in \mathbb{R}^+, \exists n_0 \in \mathbb{N}, \forall n \in \mathbb{N},$$
  
$$n \ge n_0 \Rightarrow 0 \le b \cdot g(n) \le f(n) \le c \cdot g(n)$$

## $Big-\Theta$ practice

Show: 
$$11n^2 + 14n - 18 \in \Theta(n^2)$$

Let 
$$f(n) = n^3 - n^2 + 5$$
. Show:  $f \in \Theta(n^3)$ 

Show: 
$$n \notin \Theta(n^2)$$
